## In Situ Hybridization (ISH)

**In situ hybridization (ISH)** is a method using labeled complementary DNA, RNA or modified nucleic acids sequences (probes) annealing to specific target DNA or RNA molecules in cells or tissue sections.

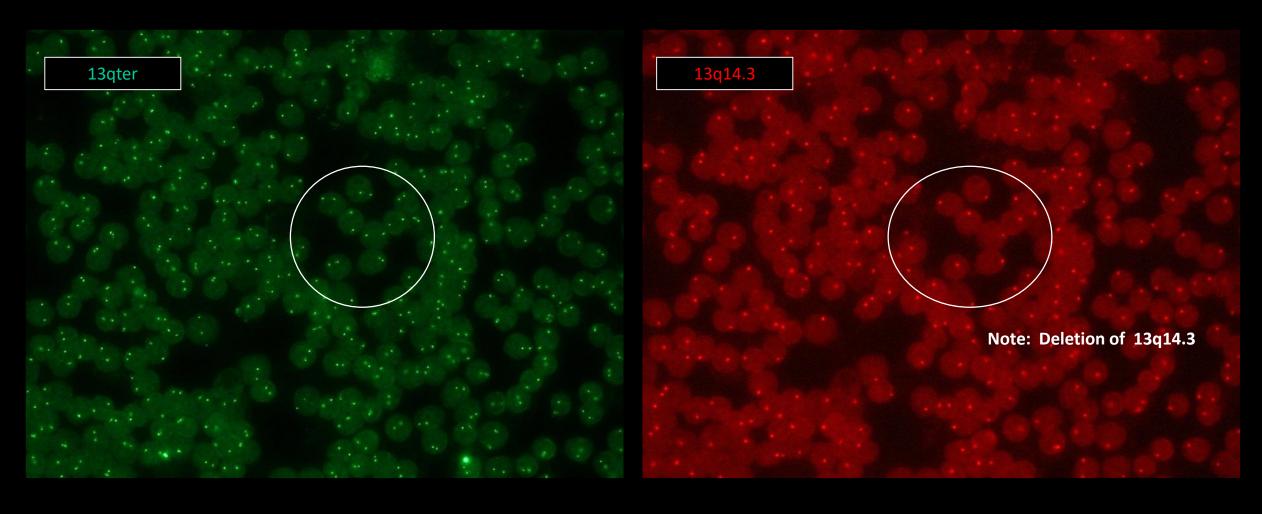

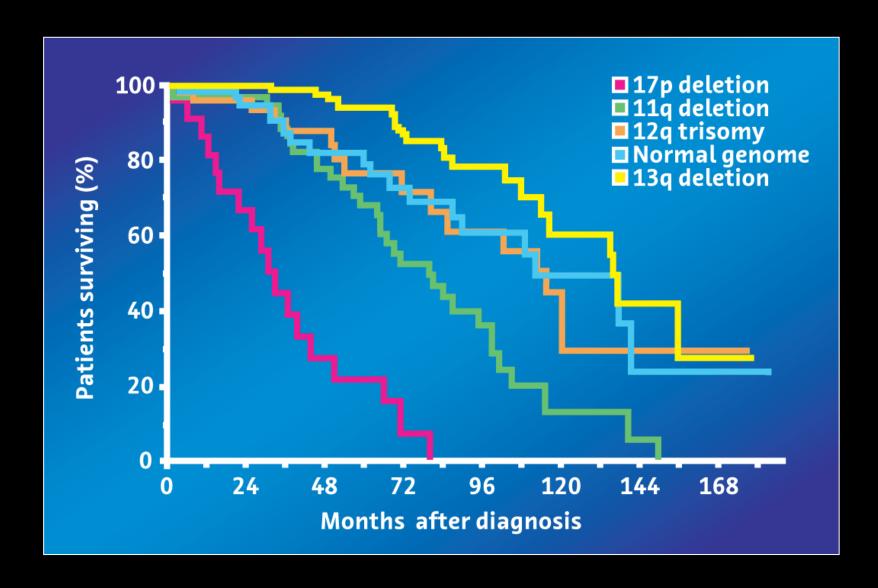

Note: Nearly 100% neoplastic B-cells (cytospun preparation)

Patient case: CLL

## **B-cell enrichment using Rosette Sep**

## Effects of genetic abnormalities on survival in patients with CLL (N=325)

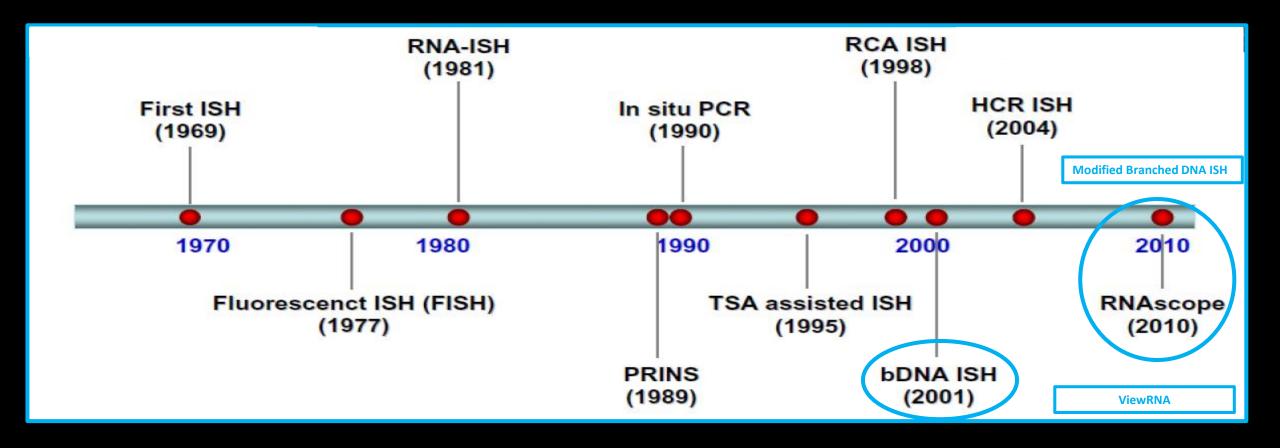

## **ISH: Typically use in the routine Pathology Departments:**

Chromogenic ISH (CISH)	Fluorescent ISH (FISH)	Research ISH (several techniques)

# **Technical Advance**

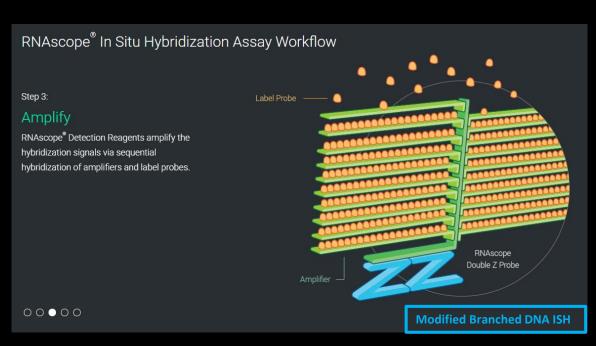

RNAscope

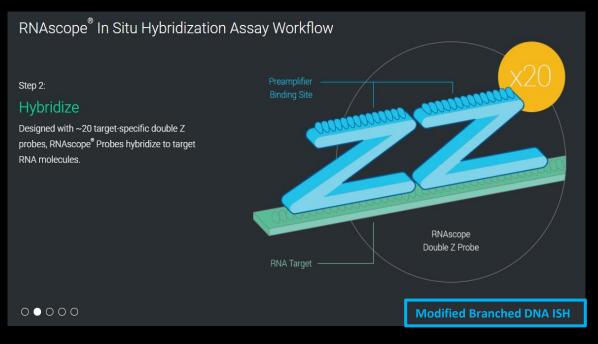

A Novel in Situ RNA Analysis Platform for Formalin-Fixed, Paraffin-Embedded Tissues

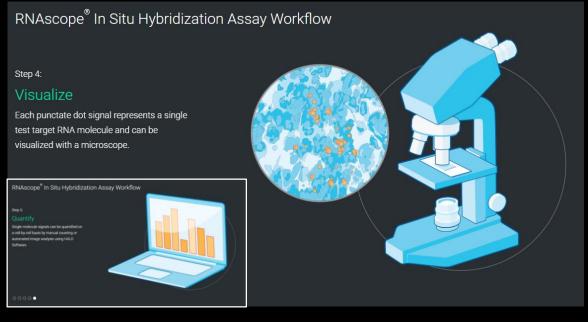

Wang F et al.

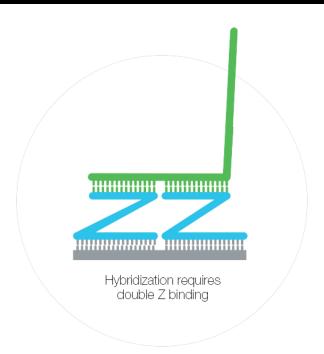

The first paper describing the use of Branched DNA ISH technology on formalin fixed and paraffin embedded tissue.

# RNAscope® Probe Design and Signal Amplification Strategy

In order to substantially improve the signal-to-noise ratio of RNA ISH, RNAscope® employs a probe design strategy much akin to fluorescence resonance energy transfer (FRET), in which two independent probes (double Z probes) have to hybridize to the target sequence in tandem in order for signal amplification to occur. As it is highly unlikely that two independent probes will hybridize to a non-specific target right next to each other, this design concept ensures selective amplification of target-specific signals.

For each target RNA species,  $\sim$ 20 double Z target probe pairs are designed to specifically hybridize to the target molecule, but not to non-targeted molecules.

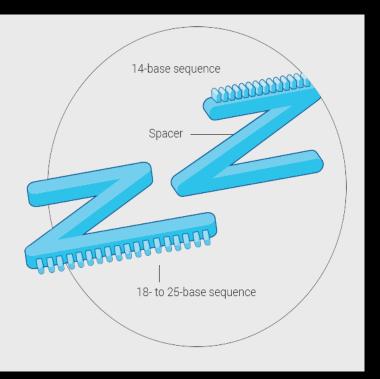

- > 45000 catalog target probes.
- > 140 species (human, mouse, rat....).
- New customer probes in two weeks (development/manufacturing).

### Each Target Z Probe Contains Three Elements

The lower region of the Z is an 18-to 25-base region that is complementary to the target RNA. This sequence is selected for target specific hybridization and uniform hybridization properties.

A spacer sequence that links the two components of the probe. The upper region of the Z is a 14-base tail sequence.

The two tails from a double Z probe pair forms a 28 base binding site for the pre-amplifier.

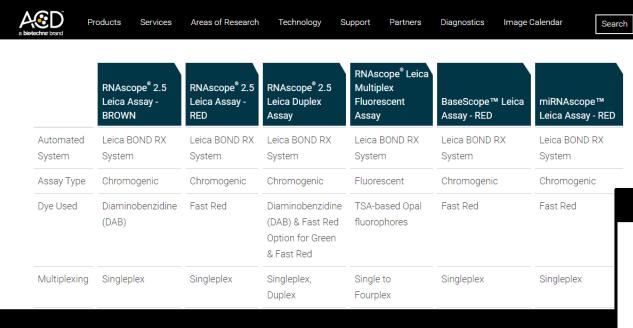

## BaseScope vs RNAscope (mRNA ISH)

	BaseScope	RNAscope
Size of target RNA	RNA 50-300 nt (bases)	mRNA > 300 nt IncRNA > 300 nt
Number of ZZ pairs pr. target	■ 1-4 ZZ pairs depending on application	Standard 20 ZZ pairs (minimum 6 ZZ pairs)
Application	<ul> <li>Single RNA molecule detection</li> <li>Exon Junction/splice variants, point mutation and short RNA sequences</li> <li>Other (e.g., gene fusion at mRNA level)</li> </ul>	■ Single RNA molecule detection

Automation	<ul> <li>Bond Rx (Leica): Single/Fast Red</li> <li>Ventana Discovery: Single/Fast Red</li> </ul>	<ul> <li>Bond Rx (Leica): Single, Duplex and Multiplex</li> <li>Ventana Discovery (Roche): Single and Duplex</li> <li>Lunaphore (Single or HiPlex/Multiomics and Proteomics)</li> </ul>
Workflow length	<ul><li>8.5 Hours (Manual/Single Staining)</li></ul>	<ul><li>8 Hours (Manual/Single staining)</li></ul>
Probes	C1 (HRP)/C2 (AP) Channels	• C1/C2/C3/C4?

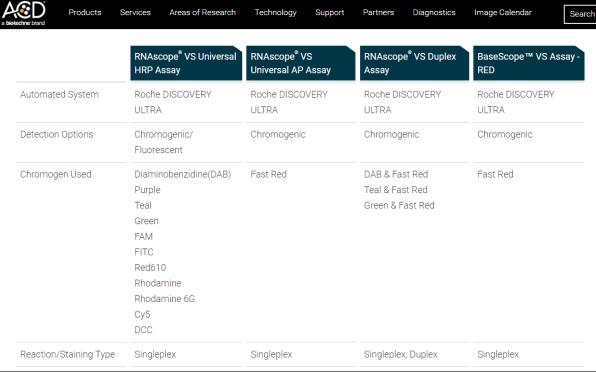

Long non-coding RNAs (IncRNAs) are a large and diverse class of transcribed RNA molecules with a length of more than 200 nucleotides that do not encode proteins (or lack > 100 amino acid open reading frame). IncRNAs are important regulators of gene expression, and IncRNAs are thought to have a wide range of functions in cellular and developmental processes.

## Base/RNAScope (mRNA ISH) - Automation

**Automation – Highly recommended** 

Manual – Labor intensive (many hybridization/protocol steps).

#### SYSTEMATIC REVIEW

#### Evaluation of the Suitability of RNAscope as a Technique to Measure Gene Expression in Clinical Diagnostics: A Systematic Review

Sameeha Atout<sup>1</sup> · Shaymaa Shurrab<sup>2</sup> · Carolyn Loveridge<sup>1</sup>

Accepted: 2 December 2021 / Published online: 26 December 2021 © The Author(s), under exclusive licence to Springer Nature Switzerland AG 2021

#### Abstract

Objective To evaluate the application of RNAscope in the clinical diagnostic field compared to the current 'gold standard' methods employed for testing gene expression levels, including immunohistochemistry (IHC), quantitative real time PCR (qPCR), and quantitative reverse transcriptase PCR (qRT-PCR), and to detect genes, including DNA in situ hybridisation (DNA ISH).

Methods This systematic review searched CINAHL, Medline, Embase and Web of Science databases for studies that were conducted after 2012 and that compared RNAscope with one or more of the 'gold standard' techniques in human samples. QUADAS-2 test was used for the evaluation of the articles' risk of bias. The results were reviewed narratively and analysed qualitatively.

Results A total of 27 articles (all retrospective studies) were obtained and reviewed. The 27 articles showed a range of low to middle risk of bias scores, as assessed by QUADAS-2 test. 26 articles studied RNAscope within cancer samples. RNAscope was compared to different techniques throughout the included studies (IHC, qPCR, qRT-PCR and DNA ISH). The results confirmed that RNAscope is a highly sensitive and specific method that has a high concordance rate (CR) with qPCR, qRT-PCR, and DNA ISH (81.8–100%). However, the CR with IHC was lower than expected (58.7–95.3%), which is mostly due to the different products that each technique measures (RNA vs. protein).

**Discussion** This is the first systematic review to be conducted on the use of RNAscope in the clinical diagnostic field. RNAscope was found to be a reliable and robust method that could complement gold standard techniques currently used in clinical diagnostics to measure gene expression levels or for gene detection. However, there were not enough data to suggest that RNAscope could stand alone in the clinical diagnostic setting, indicating further prospective studies to validate diagnostic accuracy values, in keeping with relevant regulations, followed by cost evaluation are required.

#### 1 Introduction

#### 1.1 The Developmental History of RNAscope

Gene expression involves transcription of DNA into messenger RNA (mRNA) followed by translation of mRNA to protein. Other important RNA molecules, such as micro-RNAs and long non-coding RNAs, can also play a role in

#### **Key Points**

RNAscope is a novel technology that can be used to measure gene expression (RNA).

RNAscope could be used as a complementary technique alongside existing procedures to enhance the diagnosis of disease that occurs as a result of abnormal gene expression, for example to confirm any unclear results from gold standard methods.

For RNAscope to be used as a tool to diagnose disease, further research is required to fully validate the technique so that it complies with regulatory standards and to assess cost implications for the health service.

# Systematically review of the RNAscope technique based on retrospective studies (27 articles)

- Advantages
- Disadvantages
- Clinical use?

Table 2 Advantages and disadvantages of RNAscope technique

Factor	Study no.a
Advantages	
Identify gene expression at a single-cell level within a morphological context	13, 18
Does not depend on antibodies	13
Allows the detection of mRNA as a single gene copy	12, 20
High analytical accuracy, sensitivity and specificity	1, 4, 7-9, 11,15, 17, 19-24
More reliable than IHC	3
Suppress background noise and produce better resolution than IHC	8, 15, 17, 20, 27
Reduce the risk of false-positive results	17
Its results are easy to interpret	5, 6, 8, 15, 17, 21
It is a robust and quantitative technique	11, 16, 27
It can detect tissue heterogeneity and partially degraded RNA	2, 27
Quick to perform	9, 11, 18
It can be performed automatically and manually and saves time	1, 14
Disadvantages	
It is not suitable to discriminate between viral RNA transcripts and viral DNA	7
The stain will not take place well if the samples are with poor fixation quality and the cost is much higher compared to IHC	11
In cervical intraepithelial neoplasia (CIN) cases, the negativity of RNAscope does not guarantee the absence of HR-HPV	16
RNAscope was less specific differentiating AdCC from high grade basaloid sinonasal tumors	22
In the automated system, some areas in the slides need manual selection during the scoring process	26

#### SYSTEMATIC REVIEW

## Evaluation of the Suitability of RNAscope as a Technique to Measure Gene Expression in Clinical Diagnostics: A Systematic Review

Sameeha Atout<sup>1</sup> · Shaymaa Shurrab<sup>2</sup> · Carolyn Loveridge<sup>1</sup>

#### This paper also reviewed that there was:

A close concordance rates between the results of RNAscope and molecular techniques as qPCR /DNA ISH.

A high level of variability between the results of RNAscope and IHC

#### Details that could account for the high level of variability (RNAscope vs IHC)

- Gene regulations: Transcriptional (mRNA) and post transcriptional (protein) levels
- Content (difference) between RNA and protein e.g., mutations might alter protein content
- Phophorylation/glycosylation (post-translation) can affect protein but not RNA expression
- Raw mRNA molecules (coding and non-coding sequences) might be translated differently into several proteins, and thus, could explain for the relative low CR between RNAscope and IHC.
- Other variables?

## RNAscope and use in clinical diagnostic

Am J Clin Pathol. 2013 Nov;140(5):736-46

Ultrasensitive RNA in situ hybridization for detection of restricted clonal expression of low-abundance immunoglobulin light chain mRNA in B-cell lymphoproliferative disorders.

JCI Insight. 2020 5(12); e139042

**Molecular Detection of SARS-CoV-2 in Formalin Fixed Paraffin Embedded Specimens** 

J Vis Exp. 2014 Mar 11;(85):51426

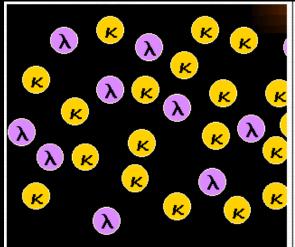

RNAscope for in situ detection of transcriptionally active human papillomavirus in head and neck squamous cell carcinoma.

## Why should we use RNAscope in a Pathology Department

- Helpful in challenging diagnostic situations e.g., detection of light chain restrictions (kappa/lambda) in B-cell Lymphomas
- Confirming mRNA findings (Nanostring profiling) which cells are positive
- Validation/verification of reaction patterns obtained with antibodies
- Lack of valid primary antibodies
- BaseScope

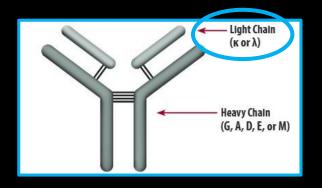

e.g. point mutation (BRAF V600E in melanomas or colon adenocarcinomas) or gene fusion products

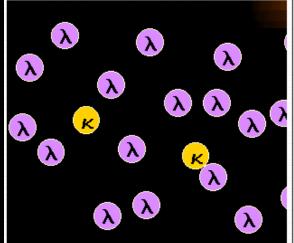

B-cell lymphomas and plasma cell disorders are characterized by showing immunoglobulin light chain restrictions and is the hallmark of discriminating reactive conditions from malignant transformation.

#### Normal, polyclonal B-cells are a mixture of kappa-B-cells and lambda-B-cells.

Our B-cells have a special feature letting us detect their clonality easily: A B-cell carries either kappa- or lambda-light chains on its surface. And normal polyclonal B-cells are a mixture of kappa-B-cells and lambda B-cells as can be seen in the left-hand figure.

#### Monoclonal mature B-cells are either kappa or lambda.

If a malignant B-cell clone proliferates this will result in a B-cell population consisting of either only kappa- or only lambda-B-cells. The latter case (i.e. lambda-monoclonal B-cells) is symbolized in the left-hand figure. Note: in rare cases we find no light chain expressed on the B-cell surface, even in a mature B-cell neoplasm. This makes the diagnosis a little bit more difficult.

#### In general:

B-cells express membranous Ig's

Plasma cells express cytoplasmic Ig's and secret Ig's to the surrounding tissue

### Demonstrations of immunoglobulin light chain restrictions in B-cell lymphomas

### **Challenges:**

- Fresh and unfixed material unavailable for Flowcytometric investigations (Standard method).
  - Kappa/lambda antibodies are used in panels with other hematolymphoid markers
- Immunohistochemistry have the tendency to be confounded by background staining.
  - Serum immunoglobulin
  - Require carefully calibrated protocol (difficult) and "optimal" pre-analytic conditions
  - Risk of false positive /negative results due suboptimal fixation
- Lack of sensitive and robust mRNA ISH technology for FFPE tissue
  - Mature B-cell lymphomas often express low level of membranous immunoglobulin (protein) and thus, low level of mRNA K/L

# RNA Scope Duplex

LPL (Lambda +)

**IGL (C2) + Kappa (C1)** 

LPL (Kappa +)

## **Advance Cell Diagnostic (RNAscope) respond:**

This means the problem is with high C2 signal that creates unspecific green signal overlapping with the red, which follows the expected pattern of the C2 (red) target.

And it turns out that this is actually something we expect for the RNAscope and BaseScope duplex assays. We <u>always</u> recommend to put the highest expressor in C1, because we know that a lot of red signal can interfere with the green signal.

However, we rarely see any problem even if customers pick C2 for a target that is a bit higher than that in C1 and we understand that it is not always possible to know this in advance.

But, Kappa and Lambda tissues are the "extreme" of this situation, where Kappa or Lambda can be very very high. And it is exactly for cases like this that we have this rule.

So, fundamentally there is nothing wrong, but we are dealing simply with a limit of the RNAscope duplex chemistry and there is no way around it if not switching the probes for samples where you see this happening.

Tissue and tissue controls

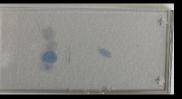

Sensitivity, Specificity and Reproducibility

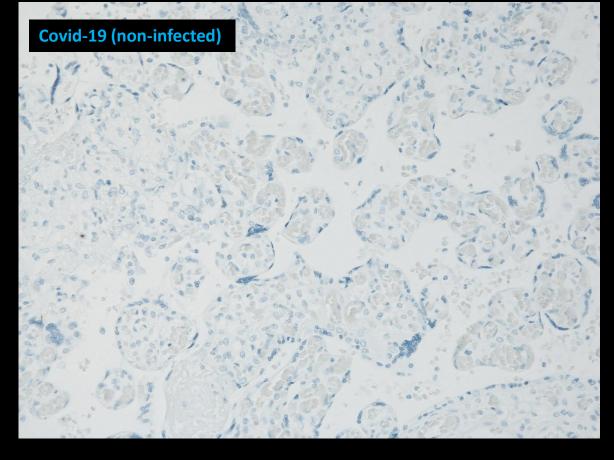

# **RNAscope Covid-19**

## Placenta

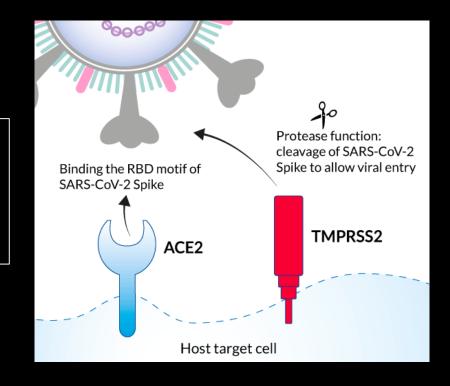

## **Transmembrane serine protease 2 (TMPRSS2)**

(Covid-19)

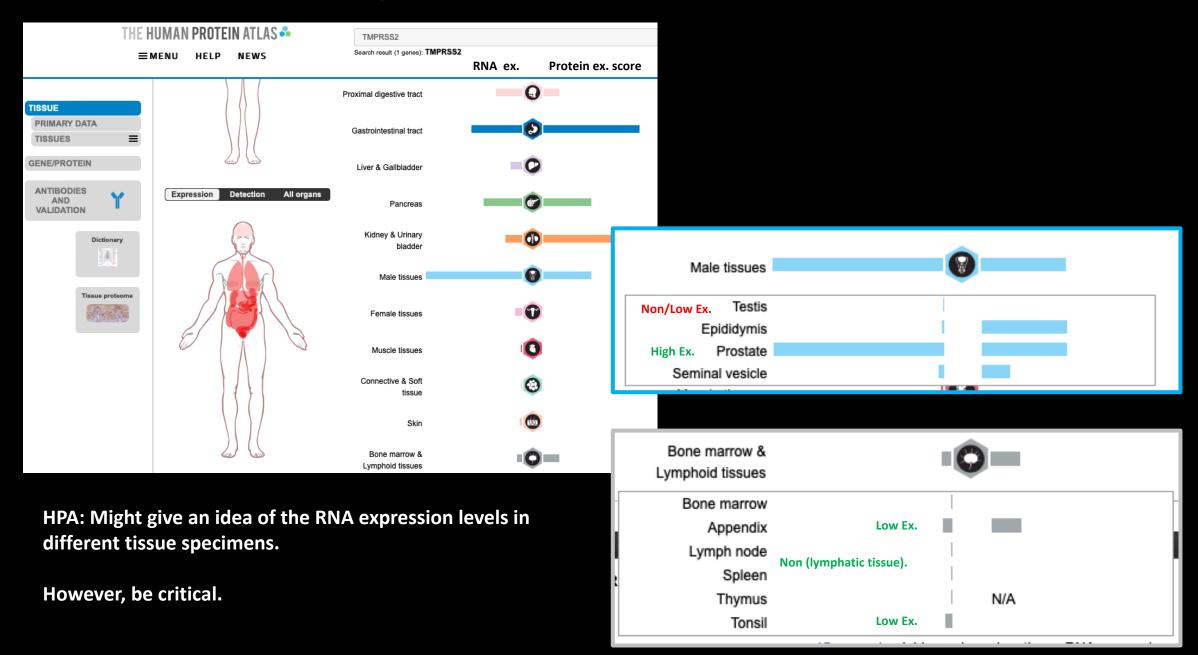

TMPRSS2 is an enzyme involved in the 'priming' of many viruses including coronaviruses such as SARS-CoV-2, allowing them to enter the body to cause disease (such as COVID-19).

Following binding of ACE2, the Spike protein is subsequently cleaved by the host transmembrane serine protease 2 (TMPRSS2) to release the spike fusion peptide, promoting virus entry into target cells

TMPRSS2 is expressed in e.g., prostate, nasal, bronchial, and gastrointestinal epithelium

## TMPRSS2 (RNA levels) – What to expect (normal tissue)?

## RNAscope TMPRSS (Discovery standard protocol, CC1 16` (97°C)/ P 16` (36°C), AMP5 12` (36°C))

## **Angiotensin-Converting Enzyme 2 (ACE2 "receptor")**

(Covid-19)

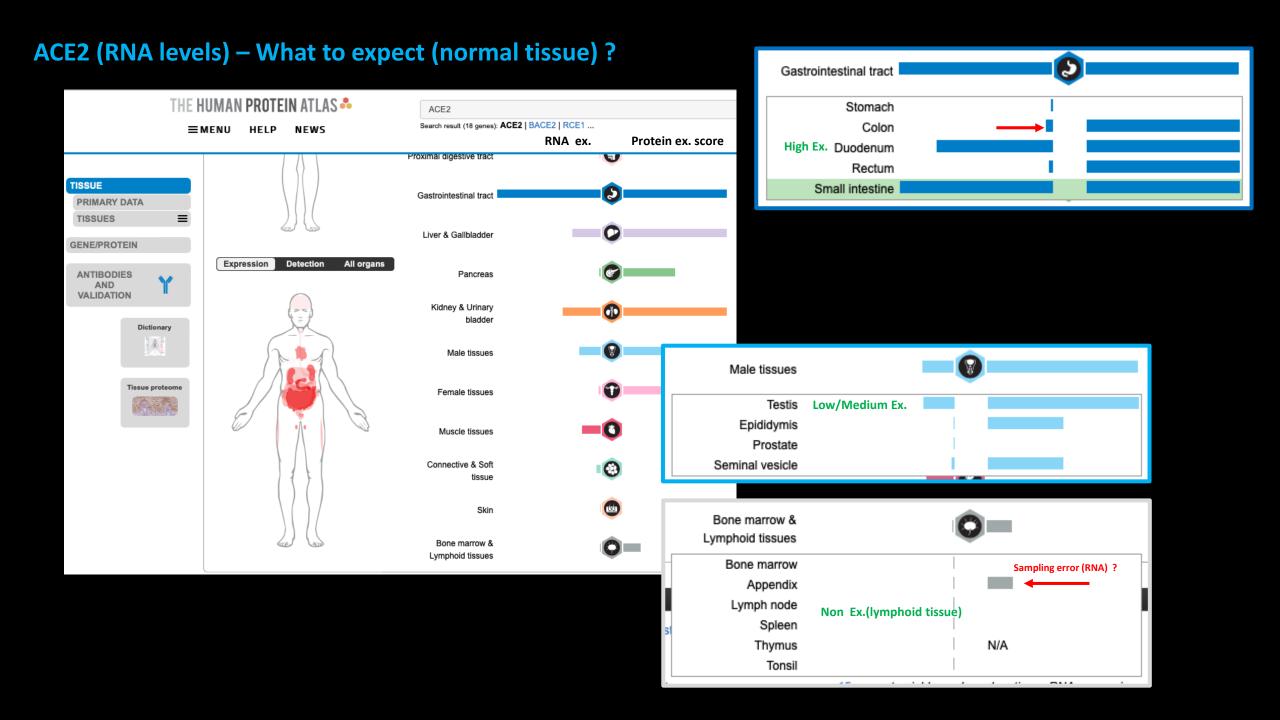

SARS-CoV-2 uses angiotensin-converting enzyme 2 (ACE2) as the receptor to mediate viral entry into host cells

Using the spike-like protein on its surface, the SARS-CoV-2 virus binds to ACE2. Hence, ACE2 acts as a cellular doorway for the virus that causes COVID-19.

ACE2 is present in many cell types and tissues including the lungs, heart, blood vessels, kidneys, liver and gastrointestinal tract. It is present in epithelial cells, which line certain tissues and create protective barriers.

- ACE2 is highly abundant on type 2 pneumocytes, an important cell type present in chambers within the lung called alveoli, where oxygen is absorbed and waste carbon dioxide is released.

## RNAscope ACE2 (Discovery standard protocol, CC1 16` (97°C)/ P 16` (37°C), AMP5 12` (37°C))

# Single-copy Gene Detection Using Branched DNA (bDNA) In Situ Hybridization

Audrey N. Player, <sup>1</sup> Lu-Ping Shen, Daryn Kenny, Vincent P. Antao, and Janice A. Kolberg Bayer Diagnostics, Emeryville, California

SUMMARY We have developed a branched DNA in situ hybridization (bDNA ISH) method for detection of human papillomavirus (HPV) DNA in whole cells. Using human cervical cancer cell lines with known copies of HPV DNA, we show that the bDNA ISH method is highly sensitive, detecting as few as one or two copies of HPV DNA per cell. By modifying sample pretreatment, viral mRNA or DNA sequences can be detected using the same set of oligonucleotide probes. In experiments performed on mixed populations of cells, the bDNA ISH method is highly specific and can distinguish cells with HPV-16 from cells with HPV-18 DNA. Furthermore, we demonstrate that the bDNA ISH method provides precise localization, yielding positive signals retained within the subcellular compartments in which the target nucleic acid sequences are localized. As an effective and convenient means for nucleic acid detection, the bDNA ISH method is applicable to the detection of cancers and infectious agents. (J Histochem Cytochem 49:603–611, 2001)

Single dots in the nuclei: Are we detecting the genes?

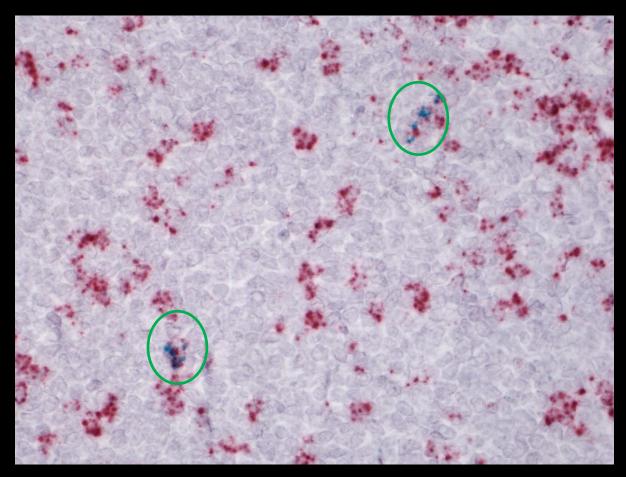

#### **KEY WORDS**

branched DNA (bDNA) signal amplification in situ hybridization (ISH) cervical cancer cell lines human papillomavirus (HPV)

## RNAscope IL17A/CD3E: With and without a DNAse pre-treatment step

Without DNAse

With DNAse (Qiagen 4')

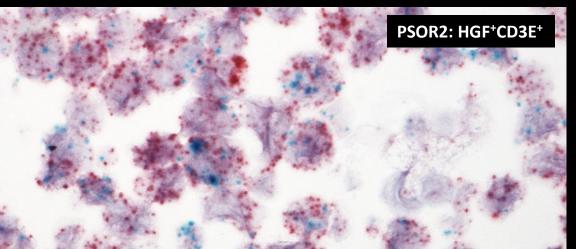

The pre-treatment with DNAse eliminated reactions related to dots in the nuclei's. Specific signals are preserved.

## **bDNA** In situ hybridization (RNAscope)

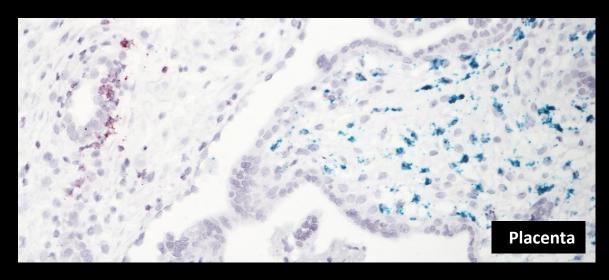

### **Summary:**

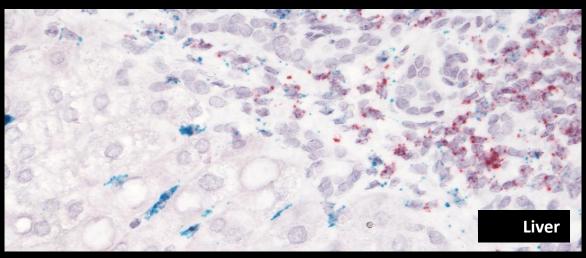

- It works, especially with the SinglePlex assay
  - Based on C1 probes (DAB) and single detection reagents
- Using Duplex Kit select the right channel of the probe
  - C1 for the most abundant expressed target mRNA (not always possible to predict)
  - Cross-reactivity and false positive result (mixed color) may be seen
- Single mRNA molecule detection be critical?
  - E.g., single "nuclear dots" could be the gene expression
- ViewRNA?

Kappa and lambda light chain mRNA in situ hybridization compared to flow cytometry and immunohistochemistry in B cell lymphomas

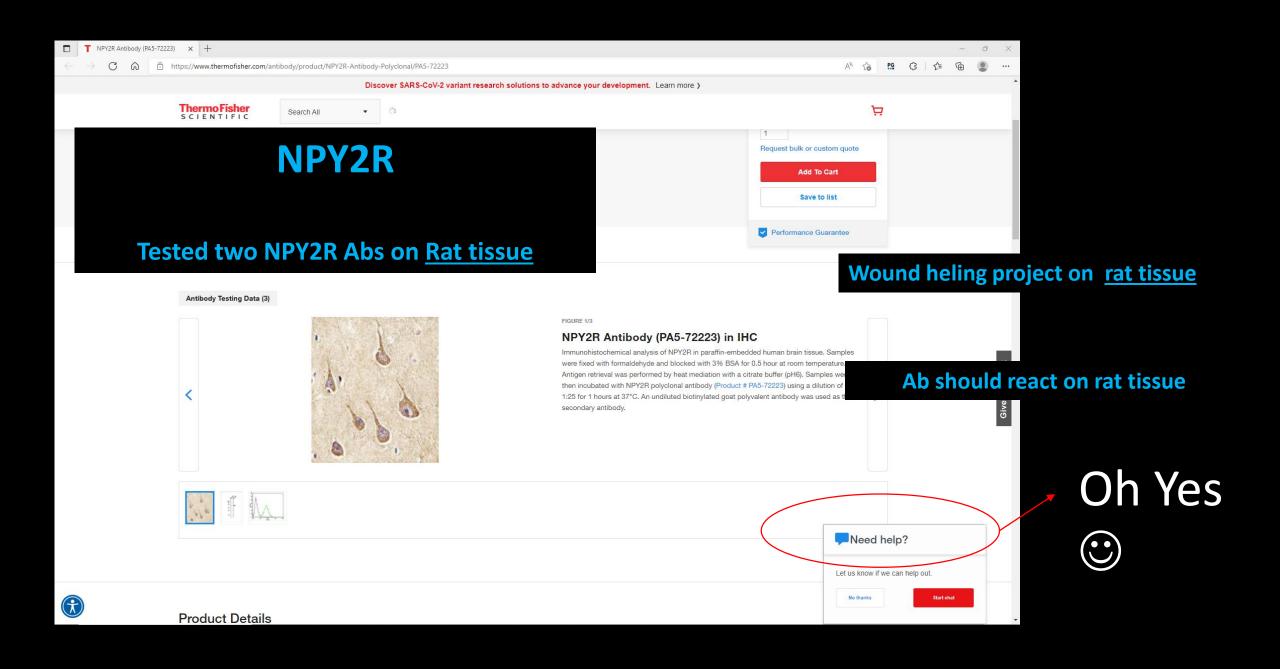

Lisa M Rimsza<sup>1\*</sup>, William A Day<sup>2</sup>, Sarah McGinn<sup>1</sup>, Anne Pedata<sup>2</sup>, Yasodha Natkunam<sup>3</sup>, Roger Warnke<sup>3</sup>, James R Cook<sup>4</sup>, Teresa Marafioti<sup>5</sup> and Thomas M Grogan<sup>2</sup>

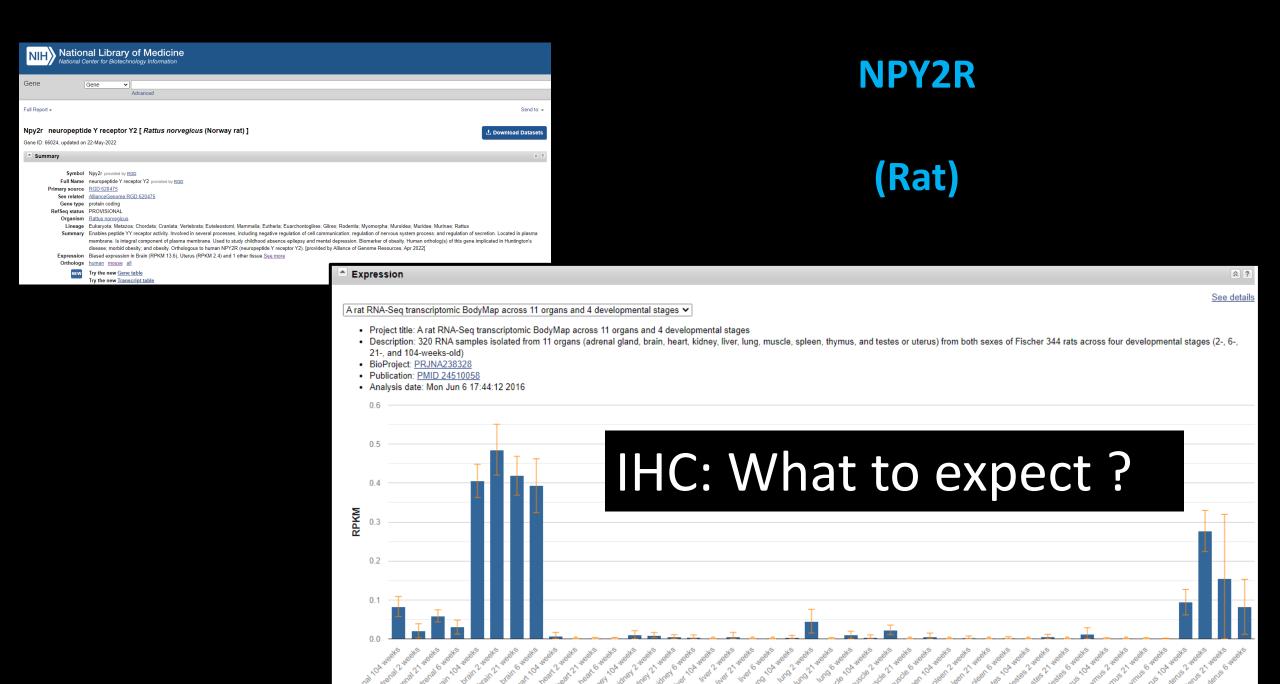

## mRNA Kappa or Lambda light chain

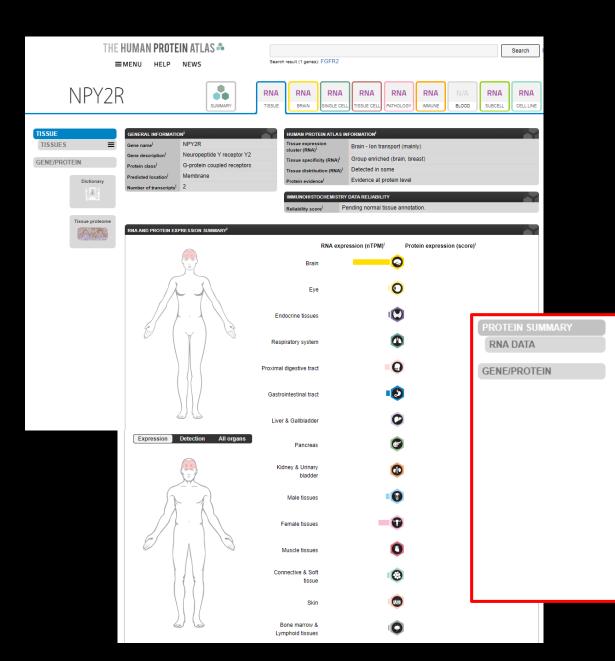

Demonstration of monoclonality in B-cell proliferations using mRNA CISH standard procedures, is most often useful in myeloma and cases with plasmacytic differentiation due to high mRNA level (Kappa or Lambda) in these disorders.

**Figure 1 Ig mRNA levels increase with B cell differentiation.** As B lymphocytes pass through stages of maturation from precursor B cells to naïve B cells to germinal center cells to post-germinal center cells then to plasma cells, the level of mRNA encoding immunoglobulin increases. Current slide-based methods are generally able to detect the mRNA levels found in the later stages of differentiation (generally in the post-germinal center stages).
